

SQL User-Defined Functions Practice Questions

Here are SQL questions to help you practice user-defined functions:

1. Calculate Total Order Quantity

Create a scalar user-defined function named `CalculateTotalOrderQuantity` that takes an `OrderID` as input and returns the total quantity of all items in that order.

- **Hint:** You'll need to use `SUM()` on the `Quantity` column within the `Orders` table.

2. Get Customer Initials

Create a scalar user-defined function named `GetCustomerInitials` that takes `CustomerID` as input and returns the initials (e.g., "JD") of the customer from a `Orders` table that has a `customername` column.

- **Hint:** You'll need to use string functions like `LEFT()` and concatenation.

3. Get Product Price by ID

Create a scalar user-defined function named `GetProductPriceByID` that takes a `ProductID` as input and returns the `UnitPrice` of that product from the orders table.

- **Hint:** You'll need to use `SELECT` to retrieve the `UnitPrice` for the given `ProductID`.

4. Count Orders by Customer

Create a scalar user-defined function named `CountOrdersByCustomer` that takes a `CustomerID` as input and returns the total number of orders placed by that customer.

- **Hint:** You'll need to use `COUNT()` on the `OrderID` column within the `Orders` table, filtered by `CustomerID`.

5. Get Employee Full Name

Create a scalar user-defined function named `GetEmployeeFullNameandregion` that takes an `OrderID` as input and returns the concatenated full name and Region (e.g., "Jane Smith East") of the customer from an `Orders` table with `CustomerName` and `Region` columns.

- **Hint:** You'll need to concatenate the `CustomerName` and `Region` columns.
